

A Shariah board decides. Someone conveys the decision. An engineer implements what they understood. The board has no way to confirm that what runs is what it ruled. Gravitas closes that gap in two directions at once – **the ruling becomes enforceable at the moment of execution, and the board that made it can see, in its own language, exactly what it authorised.**

Two products, one record. **Gravitas Protocol** is the on-chain compliance and liquidity layer: a policy registry consulted before every transaction, and migration engines that move capital atomically inside the limits an owner signs. **Gravitas Majlis** is the environment the board itself works in – the record, the calculations, the deliberation, and the vote. Majlis runs with or without a chain underneath it, which is the whole of the web2 / web3 story on page two.

THE STACK

Policy Registry

The compliance oracle. Validates assets, routers and executors against the board's terms **before** a transaction settles – a refusal at the point of attempt, not a finding afterwards.

LIVE · TESTNET

Teleport V2 / V3

Atomic liquidity migration for Uniswap V2 LP and V3 NFT positions. All-or-nothing, bounded by the slippage limits the owner signs. EIP-712 signatures, Yul-optimised on V3.

LIVE · TESTNET

Majlis

The board's own environment: matters, evidence, votes with reasoning, the toolkit of contract shapes and calculations, and the record. English, Arabic and Urdu.

SEE PAGE 2

SDK & Integration kit

A single view call integrates the registry as middleware into any tokenisation platform. OpenAPI spec, runnable mock sandbox, and six PoC scenarios that run with no meetings.

PRE-AUDIT

COMPLIANCE, IMPLEMENTED RATHER THAN ASSERTED

No *riba* interest

The intended revenue model is a service fee on a **completed migration**, never a charge for time. **Stated plainly: it is not implemented.** No fee is charged anywhere in the contracts today.

No *gharar* uncertainty

Deterministic routing. A simulation API gives the exact outcome **before** execution, and execution is atomic – no partial fills, no discovering the result afterwards.

No *maysir* gambling

Protocol-level filtering of speculative and gambling-related tokens, enforced by the registry rather than by policy documents.

Asset verification the board's list

An on-chain whitelist maintained by governance. Nothing becomes permissible by administration: **changing a standard requires a ruling in force, not a button.**

48h

Timelock on every policy change, at mainnet

\$3T+

Islamic finance market this is built to admit

WHAT IS NOT TRUE YET

The protocol is on **testnet, not mainnet**. Shariah certification is **in progress** through advisory review and is not complete; no date is claimed. The service fee is **designed and not built**. Before production, ownership of the registry transfers to the timelock, so no policy change can take effect inside 48 hours. Everything still open is recorded in the repository rather than left to be discovered.

The vote is the signature. What a scholar signs is a hash of the **exact operative terms** shown at the moment of voting — so *did the board approve what was deployed* is a comparison, not testimony.

Majlis holds the whole of a board's work: matters with a plain-language brief, the operative terms, what is deliberately **not** being decided, the evidence each argument rests on, every vote with its reasoning, and dissent kept rather than smoothed away. The record is append-only — a correction supersedes, and what stands is derived by the chain of decisions, never by a timestamp.

TWO WORLDS, ONE INSTRUMENT — THIS IS THE WEB2 / WEB3 ANSWER

WEB2 · NOTHING ATTACHED

A document to send

The ruling is a document, assembled from the record — the question as put, the operative terms, who voted and why, any dissent — and somebody in the institution sends it.

The last step is a person, and Majlis says so on the screen. A board that assumed the bank had been told would be assuming the one thing this application cannot do.

- › **Everything runs inside the app** — intake, evidence, quorum, timelock, the vote, the file.
- › **Maximum automation** up to the boundary: figures are read out of documents and *proposed*, never filled in.
- › **It issues a PDF** — the fatwa, the audit export with its integrity hash, the annual account. Ready for the bank.

WEB3 · REGISTRY ATTACHED

Read before every transaction

The terms are read before every transaction that depends on them. A transaction that would breach one does not execute — refused at the attempt, not discovered after it.

Nothing to send, no interval to drift in. The document still exists — as the account of the decision rather than the instrument of it, because a chain is not a record a person reads.

- › **The same app, the same record, the same vote.** Enforcement is one adapter; its default is nothing.
- › **Instead of a PDF, an entry in the registry** — the operative terms written where they are consulted.
- › **The address is shown**, with its reachability — not a reassurance to be taken on faith.

The same instrument either way: switching the registry on changes nothing about how the board works.

WHAT IS IN THE BOARD'S HANDS

The library

19 contract shapes, 89 conditions, 10 families — sale, lease, partnership, agency, securities, exchange, securing an obligation, protection, and combining contracts. Every condition carries what must be true, *why* it matters in terms of what goes wrong without it, and how it is evidenced.

The calculations

Screening, purification, zakat, profit distribution, tradability, exchange, late payment. Exact decimal arithmetic, one rounding per formula. **Majlis computes; it never concludes** — the ratio and the method are the board's, and it refuses to choose between overlapping bands, because choosing is a ruling.

The record

Append-only, and searchable across every matter, rule, term, source and stated reason. A one-action audit export carrying an integrity hash. Five deadlines on one calendar — derived from the record, never stored, so none can quietly disagree with it.

THE SEQUENCE — USE IS EARNED BEFORE IT IS REQUIRED

STAGE ONE · BUILT

Record and comprehension

The record, the briefings, the guide. No governance function, so a board takes on no obligation while it decides whether it trusts the thing.

STAGE TWO · BUILT

Deliberation

Matters, evidence, simulation, quorum, discussion, votes with reasoning — the whole process, with nothing yet resting on it.

STAGE THREE · NEXT

The vote becomes the signature

Threshold signing moves in. Key management is the part most likely to fail, and it fails for human reasons: no seed phrase is ever shown.

STAGE FOUR

Plurality

Several boards and institutions, cross-referenced. Assumed from the first line of code: `boardId` is on every rule already.

1,526 Tests passing, server and client

918 Strings, complete in all three languages

19 Contract shapes with their conditions

0 Rulings the software gives on its own

WHAT IS NOT TRUE YET

Stage Three is **not built**: signing authority is still outside Majlis, so a vote is a recorded position rather than an operative act. The Arabic and Urdu are **a first pass awaiting a native reviewer**, and the application says so on arrival, in the reader's own language. Majlis **names what it cannot do where a person would look for it**: a control that cannot be honoured is absent, not disabled.
